

Essential Question: What are the properties of an angle bisector?

- An angle bisector is a segment, ray, line or plane that intersects an angle to form two adjacent congruent angles.

- The distance from a point to a line is the length of the perpendicular segment from the point to the line.

Angle Bisector Theorem: If a point is on the bisector of an angle, then it is equidistant from the two sides of the angle.

In other words:

If $\angle FAD \cong \angle EAD$, then $FD \cong ED$.

Converse of the Angle Bisector Theorem: If a point is in the interior of an angle and is equidistant from the sides of the angle, then it lies on the bisector of the angle.

In other words:

If $FD = ED$, then $\angle FAD \cong \angle EAD$.

Example 1: Can you conclude that P is on the bisector of $\angle A$? Explain.

NO, Distance from bisector to the sides of the angle are not equal.

- When three or more lines (or rays or segments) intersect in the same point, they are called **concurrent lines**. The point of intersection of the lines is called the point of concurrency.
- The point of concurrency of the angle bisectors of a triangle is called the incenter of the triangle.

Sketch a picture of the incenter.

The incenter is always inside a triangle.

Theorem: The angle bisectors of a triangle intersect at a point that is equidistant from the sides of the triangle.

Since the incenter is equidistant from the sides of a triangle, then an inscribed circle can be drawn. An inscribed circle is a circle with a center at the incenter and a radius that is the distance to the sides.

Example 2: If point Y is the incenter, find YR and MT if TY = 26 and RT = 24.

$$x^2 + 24^2 = 26^2$$

$$x^2 = 100$$

$$x = 10$$

$$\boxed{YR = 10}$$

Key

Essential Question: What are the properties of a perpendicular bisector?

- A **perpendicular bisector** is a segment, ray, line or plane that is perpendicular to a segment at its midpoint.

Perpendicular Bisector Theorem: If a point is on the perpendicular bisector of a segment, then it is equidistant from the endpoints of the segment.

In other words:

If \overline{DF} is the perpendicular bisector of \overline{AB} , then $AD = BD$, $AE = BE$, and $AF = BF$.

Converse of the Perpendicular Bisector Theorem: If a point is equidistant from the endpoints of a segment, then it is on the perpendicular bisector of the segment.

In other words:

If $AD = BD$, $AE = BE$, and $AF = BF$, then, \overline{DF} is the perpendicular bisector of \overline{AB} .

Example 1: Can you conclude that C is on the perpendicular bisector of \overline{AB} ? Explain.

no, since $AC \neq BC$

- A **perpendicular bisector** of a triangle is a segment, ray, or line that is perpendicular to a side of the triangle at the midpoint of the side.
- The point of concurrency of the **perpendicular bisectors** of a triangle is called the Circumcenter of the triangle.

the circumcenter of an acute triangle is inside the triangle

the circumcenter of a right triangle is on the hypotenuse

the circumcenter of an obtuse triangle is outside the triangle

Theorem: The perpendicular bisectors of a triangle intersect at a point that is equidistant from the vertices of the triangle.

Example 2: If point O is the circumcenter, find MO, PO, PS, PR, and MN.

$$\begin{aligned} MO &= 26.8 \\ PO &= 26.8 \\ PS &= 22 \\ PR &= 26 \\ MN &= 20 \end{aligned}$$

Example 3: Cassie, Jim, and Sal are old college buddies that have moved apart. They want to get together. To be fair, they want to find a location that is the same distance for each of them to travel. How could they locate that spot?

Find incenter or circumcenter
